Project report submitted in partial fulfilment of the requirement for the
MSc in Computer Science

September 2015

Abstract

This project report presents my research and the development of a prototype web application to assist users with Autism when they search the web. The system has modelled user interactions with the search process into a user profile for this category of users, integrating insights from the core features of autism into the model. The system is integrated with an infra-red, motion controlled, user interface component to assist users with Autism during search. The project provides insights into how search can be improved for users with Autism.

This project is substantially the result of my own work, expressed in my own words, except where explicitly indicated in the text. I give my permission for it to be submitted to a Plagiarism Detection Service. This proposal may be freely copied and distributed provided the source is explicitly acknowledged.

Definitions

Autism	Autism is amongst the most common neuro-developmental condition and it is currently estimated that 1/68 children meet criteria for Autism Spectrum [5]. Autism is five times more common amongst boys than girls (1/42 boys, and 1/189 girls). According to the Diagnostic and Statistical Manual (2013), Autism is characterised by persistent and early deficits in reciprocal social interaction and repetitive behaviours. Individuals vary from high functioning to low functioning (along a spectrum), with behaviours emerging around 2 to 3 years of age.
Stereotyped User Model	Stereotyped user models infer characteristics about a user from data gathered from other users within that distinct subset. They can be built quickly using clusters of characteristics of groups of individuals.

Search Engine Measures

Precision

The field of information retrieval defines precision as the fraction of retrieved documents that are relevant to the query.

$$Precision = \frac{|(relevant\ documents) \wedge (retrieved\ documents)|}{|(retrieved\ documents)|}$$

Recall

The field of information retrieval defines recall as the fraction of relevant documents that are retrieved by the search query.

$$Recall = \frac{|(relevant\ documents) \wedge (retrieved\ documents)|}{|(relevant\ documents)|}$$

1 Introduction

This project report presents my aim to research and develop a prototype web application for people with Autism when they search the web. Despite Autism being amongst the most common neuro-developmental condition (1/68 children meet criteria for Autism Spectrum [5]), no user model has yet been developed for Autism within Search.

1.1 Background Research

According to the Diagnostic and Statistical Manual [5], Autism is characterised by persistent and early deficits in reciprocal social interaction, so interaction with computers is prominent in this group. It is also well established that individuals with Autism are more engaged when using technology that is receptive and interactive (e.g., games, responsive consoles, motion controlled devices) compared to technology that is not [14]. This project will combine interactive, motion recognition hardware with search to also improve the UI (user interface) of search for individuals with Autism.

Research has shown that people with Autism are less context-sensitive and prefer a more detail-focused processing style [19]. There is good reason to postulate then, that web-search queries are formed very differently to the typical population. Generally speaking, individuals with Autism prefer, and are more likely to engage in an item-specific, or detailed processing style, resulting in web-search queries that are more likely formed of single-order associations. In addition to a detailed, item-specific processing style, individuals with Autism are also less likely to engage in a contextual processing style. For example in a search for ‘Guitar’, a contextual style of processing would imply an awareness that the word is related to ‘Piano’, but also that both words are hierarchically related to ‘Instrument’. In day to day life, a major factor determining the effectiveness of working memory (the transient holding and processing of information for updating, learning and comprehension), and the amount and quality of information that an individual can recall and enter into the web-search, is greatly influenced by the number of cues that are available at the time. For example, if presented with a list of 50 items to remember, you are more likely to remember that I presented ‘Zebra’ if I tell you that I presented an animal. This type of ‘cued’ recall can be used to bolster recall of information for people with Autism, and is a technique that will be applied in the current project.

1.2 The Problems with Current Web-Search

The Internet is one of the largest resources of information. Search engines allow users to collate hundreds of links on a single topic, using only a few words

or phrases. The typical user sorts the returned results into ‘relevant’ or ‘irrelevant’ categories, flexibly shifting (mentally) between one result and the next, to determine the relevance of each page returned by the search engine. Search allows the user to assimilate the information on the page into their knowledge and is an important learning tool. For people with Autism, the requirement is no different, however, current search is not adequate. A large body of research has shown that ‘mental shifts’ are a known area of weakness for people with Autism [9]. The information is therefore harder to assimilate or learn, and judging the relevance of each document becomes near impossible. One successful therapeutic technique to increase the assimilation of information for individuals with Autism is to present it in clearer, smaller amounts [25]. This technique avoids overwhelming individuals, and although less information is presented as a whole, whatever is presented to the user becomes ‘digestible’ and ultimately, the information as a whole becomes more understandable.

One of the first aims of the current project was to build a synthesis of three leading search engines, to ensure the best possible results were retrieved and presented to the user. The first stage was to therefore build the combination search engine and test the results on a user group with Autism. The goal of the research was to understand if the synthesis of the search engines enhanced search experience (in other words were users happy with the combination search), or, whether the results introduced redundancies or oddities in the results (some users may not use a certain search engine because they do not find the results helpful).

Search queries usually fall into one of three broad categories [10]. ‘Do’ queries which characterise transactions between the user and the search engine, for example when the user wants to do something such as *buy a plane ticket*, *listen to a song* or, *download a screensaver*. ‘Know’ type queries, which are informational in nature, usually covering a broad topic, for example, the *name of a band* or *restaurant in London*, *trucks*, or *Colorado*. The third broad category is ‘Go’ type queries, which are navigational in nature, for example, searching for a particular home page on the web, *YouTube* or *American Airlines*. There are also many stages to the search process [10]. After identifying the information need, the user must formulate a search query. The user must browse through results once the query has been entered into a search engine. The whole process can be repeated if the user is not satisfied.

1. Experience the need for an answer, solution, or piece of information.
2. Formulate that need in a string of words and phrases, also known as ‘the query’.
3. Enter the query into a search engine.

4. Browse through the results for a match.
5. Click on a result
6. Scan for a solution, or a link to that solution.
7. If unsatisfied, return to the search results and browse for another link or ...
8. Perform a new search with refinements to the query

This project report presents the development and evaluation of a prototype web-browser based application to assist users with Autism when they search the web. The application is hereafter referred to as Jellibeans¹. Jellibeans utilises gesture and hand movement data recorded using the Leap Motion Controller (LEAP).

In programmatic terms, Jellibeans is designed to implement a research-guided user model in search. The development of this user model consisted of iterations of the ‘research, development, test, evaluate’ lifecycle. I conducted research to identify the preferences within search, and the differences in user queries formed by individuals with Autism, by conducting surveys and collecting and analysing search behaviour patterns from people with and without Autism. Using these data I built a set of features into search, to guide the user through forming a more complete search query. Development and evaluation included the implementation and testing of the features, and further implementation and revision of the software to enhance the search process and the precision of the search engine for the users’ intended search query.

Jellibeans integrates a motion controlled user interface (UI) using the LEAP motion controller. The interface is very dynamic as opposed to static, and can hold users’ attention for longer periods of time. In the past, users with Autism have struggled to maintain their attention to sift through the large number of search results. In line with the attention difficulties individuals with Autism face, Jellibeans has been designed to reduce the amount of text on the search results page, presenting only 3 results per page, instead of the default 10.

1.3 Design Patterns for Web Applications

Search engines like Google apply strong reduction techniques to navigation of the web. For example, one common way this reduction pattern is implemented is by assuming the behaviour of the current user is similar to the behaviour of

¹Jellibeans are a rainbow of colours, different sizes and shades, and the name represents the difference in style of processing of individuals with ASD.

other users in similar situations. This is often seen in recommendation engines, e.g., Amazon. The principle applied by Google is to ‘make it easy’ for the user [15], by assuming that users form search queries similarly, and returning similar results to those users.

As we have seen in the introduction, users with Autism behave in different ways to typical users when navigating search. Users with Autism do not use the same key phrases when looking for documents with several attributes, i.e., queries that would be best formulated using several iterations of search, or multiple search parameters. This leads to an ineffective search; one that requires users to sift through results which are in large-part irrelevant, and a bad user experience. Parametric search queries allow users to define parameters in an in-

creasingly logical and structured way. As an example, consider the experience of searching for flights to a particular holiday destination, or for a person. This requires high cognitive ‘load’ (remembering and manipulating arrival, departure, destination, timings, airlines, seat preferences etc.) so searches are often structured using fixed options (see Figure 1).

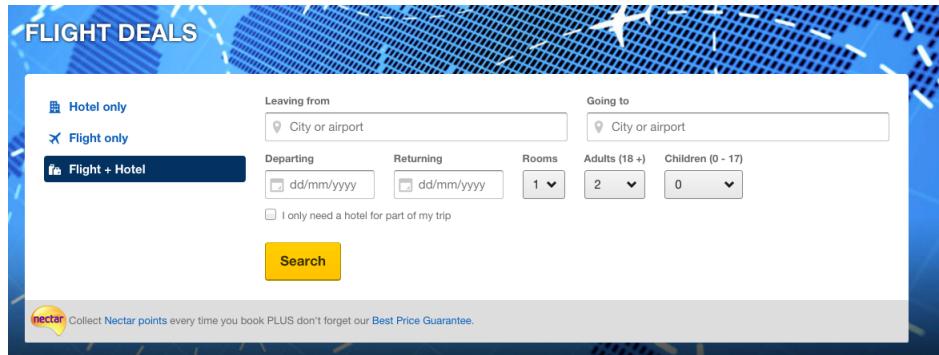

Figure 1: Expedia Parametric Search Example

For typical users, parametric search is more structured, and in some circumstances seems more natural than a free keyword search. It makes search queries easier to formulate in situations where there is a high cognitive load. We can apply this idea to web search for people with Autism, by asking them to enter criteria that can be applied to subgroups of search queries. Parametric search can assist the user with capturing the search parameters that are useful for a query it does not ultimately reduce the number of search results returned; the possibility of a large result set is most definitely true. However, when used in addition to the original search query itself, the parametric search will refine the user’s search results in line with their search query, ultimately

leading to a higher precision for the search engine. One of the aims of the study is to reduce the amount of textual information on the webpage presented to the user, so the solution implemented here tries to find a balance between these two aims.

1.4 Motion controllers

Individuals with Autism have poor attention [3]. The static 2-dimensional interface of many current search engines is unlikely to maintain adequate (sustained) interest levels. Individuals (and especially teenagers) with Autism spend a substantial amount of their time using computers, web, portable or console devices [24], as they find these more stimulating and attention-grabbing. For these individuals, computer-based technologies provide a stable, consistent learning environment that can be customized [21]. Furthermore, motion recognition devices can be programmed to make consistent responses to environmental triggers. These controlled and interactive environments have shown promise for improving social communication skills and reducing repetitive behaviours [11]. For the current project a motion-controlled learning environment will be bolstered to improve attention within search for people with autism.

Figure 2: UI component for the project [12].

1.5 Aims for Jellibeans

Jellibeans is a prototype search tool that assists users with Autism search and navigate the web. As search can be compartmentalised into 'Do', 'Know' and 'Go' type queries, it provides a natural way to tackle the issue of simplifying the search process for people with Autism. Users first identify the type of search they would like to carry out. Then Jellibeans better phrases a question to guide the user through their informational demand. Each stage of the search flow process (see Section 8, is better tailored towards providing a concrete and unam-

biguous experience for the user with Autism, and reducing the amount of text on the page.

When using Jellibeans, users are assisted through the process of formulating a search query (much like a parametric search engine form for example when you buy a car, you fill out many criteria which must be simultaneously searched for). Concretely phrased questions are aided by suggestions that appear laterally on the page.

The user can add these suggestions into their search query without the need to type them in, just by using natural hand movements, tracked by the LEAP motion controller. The UI component makes the experience of searching the web more interactive and receptive for user input. The suggestions also serve as cues for the user, and to simplify the search process for them.

The implementation of a parametric-like search means the process of forming a query is more tightly defined and predictable for the user compared to the current systems for web search. The size of the result-set is also reduced, and adapted towards users with Autism.

Each of these prototype features were tested on a group of users with Autism². The final product will be integrated in the web browser and within a motion-controlled environment. The prototype will be modified accordingly in line with the outcome of several stages of user research.

The core features of Jellibeans are:

1. A web-based search tool, that uses a *stereotyped* user model of Autism to filter search results. The features of the model were determined following analyses of survey responses gathered from individuals with Autism or a high occurrence of autism-like symptoms. The survey was administered online using a web-based survey engine [26], and focused on identifying the differences in user search query generation for people with autism). The user model for Jellibeans also takes into account the user's demographic data and other group-wide characteristics have been inferred from the Autism subset of users.
2. Jellibeans implements a parametric-like search to present search results in the context in which they were searched. Jellibeans returns small snippets on the results page (the result page is not verbally-overloaded).

²Autism diagnostic status was determined using the Autism Quotient, which strictly speaking is not a diagnostic assessment tool. However the measure has a 79% sensitivity to Autism if the user scores above 32 on the measure.

3. Jellibeans prioritises results which have first-order semantic relations to the query words. Jellibeans employs a boolean 'AND' between each query word searched for, so that results are more likely first order semantic relations to the searched query.
4. Jellibeans implements within a motion controlled UI which uses the LEAP controller. This makes search more interactive and receptive for users. The LEAP also works to maintain the attention of the user.
5. A prior iteration of Jellibeans implemented a combination search web application that synthesised the results from three of the largest and most popular engines; Google, Bing and Yahoo [20]. However, feedback from users during the user-testing phase suggested the feature should be dropped. The development and testing of the feature is presented in the current report, as it demonstrates how Jellibeans has evolved after gathering user feedback.

2 Project Trailer

Jellibeans is a web-browser based application to assist users with Autism when they search the web. Jellibeans can be found at <http://esha.mseth.co>, and the wireframe sketch and user flow can be seen in Figure 3.

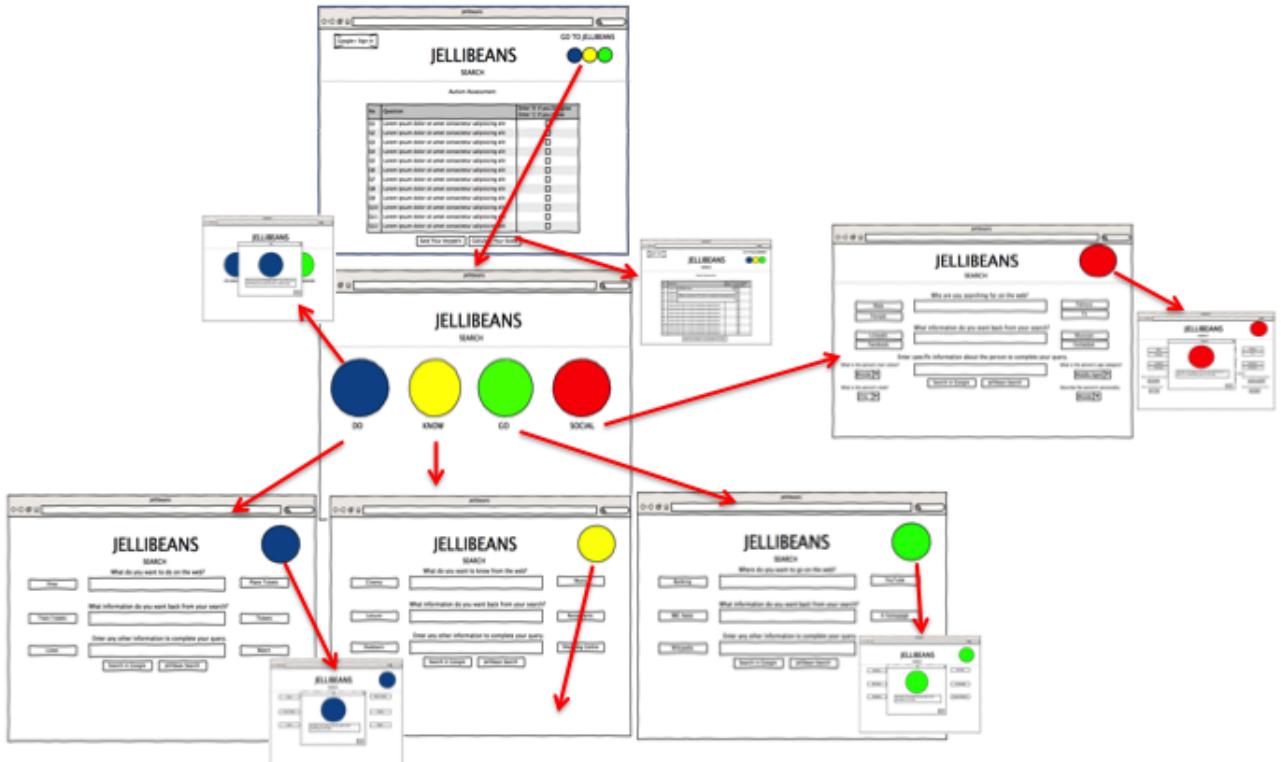

Figure 3: Wireframe Sketches for Jellibeans User Flow

Jellibeans was integrated with Google+, to allow the user to sign in and have their profile picture and name displayed, enhancing the feel of a personalised search engine (see Figure 4).

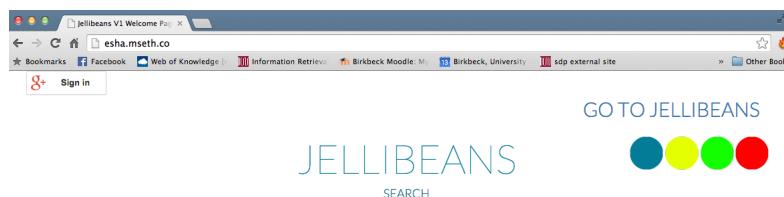

Figure 4: Using the Google+ API Allowed the User to Sign In and Retrieve User Name and Profile Picture.

Jellibeans employs a parametric-like search, and includes *suggestions* to guide the user towards forming succinct and accurate search queries (see Figure 3). Once signed in, the user can fill out the Autism Quotient and Jellibeans get feed-

back regarding their autism symptomology. The Autism Quotient [1] is a Psychological assessment and validated screening tool for autism spectrum disorders. Users can also save their responses for each question to a local file for their reference.

The screenshot shows a web browser window with the URL <http://esha.mseth.co/social.html>. The page title is "JELLIBEANS" with the subtitle "FORM YOUR SEARCH QUERY". There is a large red circular icon on the right side. The form consists of several sections:

- Who are you searching for on the web?**: Options include "Male" and "Female".
- What information do you want back from your search?**: Options include "Famous" and "TV".
- What is the person's hair colour?**: Options include "LinkedIn" and "Facebook".
- What is the person's style?**: Options include "Musician" and "Comedian".
- Enter specific information about the person to complete your query.**: A text input field.
- What is the person's age category?**: A dropdown menu.
- Describe the personality of the person**: A text input field.

At the bottom are two buttons: "Search in Google" and "Jellibeans Search".

Figure 5: An example page from Jellibeans: the Social Query page.

Jellibeans web application is integrated with a motion controlled user interface, the LEAP controller (see Figure 6) giving the application a receptive and interactive user interface.

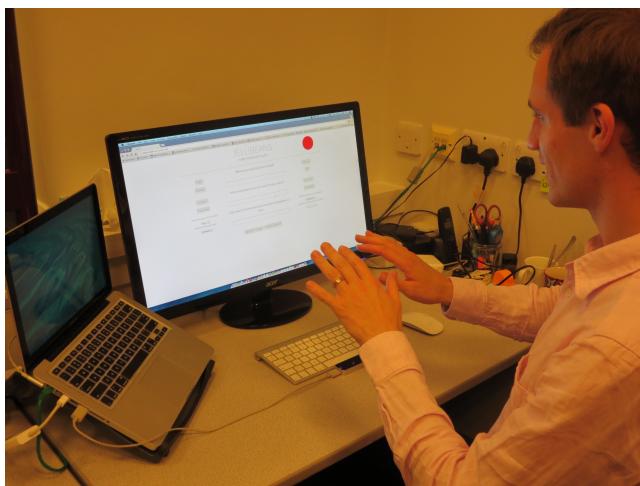

Figure 6: User Forming A Jellibeans Search Query with LEAP Using Both Hands.

Jellibeans prioritises and displays the three highest precision search results for

users. Recall of the search engine is sacrificed in line with the demands of the user model, to have less textual information on the page.

Jellibeans reduces the amount of text on the webpage by having results display on a modal (a hovering display panel on the page) which can be easily closed, and reopened to display results (see Figure 7). Due to the nature of parametric search, strict boolean operators used in Jellibeans, and the reduced number of search results displayed, the results from Jellibeans are a direct semantic relation to the search query.

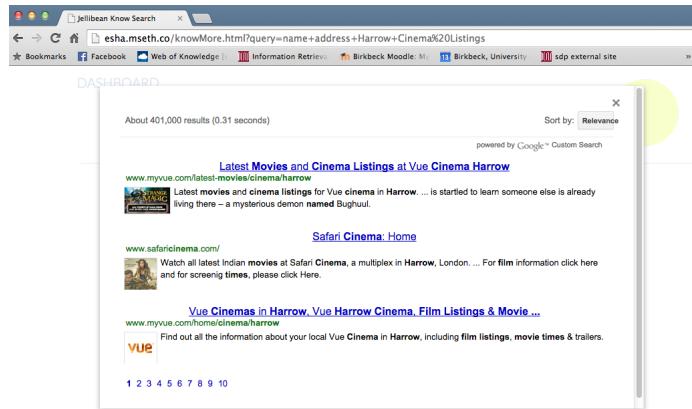

Figure 7: Top 3 results are presented back to users in a modal to reduce information on the page. The modal can easily be closed and reopened.

3 Product Specification

Jellibeans consists of 4 main modules.

1. A combination search engine that synthesises the search results from Google, Bing and Yahoo. The aim of this feature is to increase recall of the engine. The feature has been tested with a sample of users with Autism, and typically developing individuals to ensure that the combination search engine enhances search experience without introducing redundancies.
2. Jellibeans integrates with Google+ to retrieve user profile data to enhance the feel of a personalised search engine. Once signed in, users complete a diagnostic assessment of Autism (the Autism Quotient [1]). Users can save a copy of their diagnostic information to a local file on their computer.
3. Parametric Search Process. Jellibeans allows the user to break down their search query into smaller manageable questions, i.e., into 'Do', 'Know', 'Go',

‘Social’ queries. The process reduces ambiguity of forming a search query. Jellibeans provides suggestions or cues for users to assist them with forming a search query, and to help ease some users need of a ‘perfect’ search query.

Jellibeans will prioritise and display the three highest ranking search results for users. The overall goal of this feature is to reduce the amount of text on the page, to minimise the chance of overwhelming users and to retain as high precision of the search results as possible.

4. Motion Controlled User Interface. Jellibeans is a LEAP enabled website. The motion controller provides an interactive search experience, which maintains user attention.

4 System and Software Architecture

4.1 3-tier Architecture

A client-server software architecture was used for Jellibeans. The user interface and motion controller formed the presentation layer, the logic layer was made up of the JavaScript code used to implement the custom search, and storage of data in the data store were maintained as three distinct modules. The advantages of this type of design is that it allows each of the tiers to be modified, upgraded or replaced independently of one another. For example, if Jellibeans were to be implemented with another motion controller (e.g. the Oculus VR Rift), it would only impact the Presentation tier (see Figure 8).

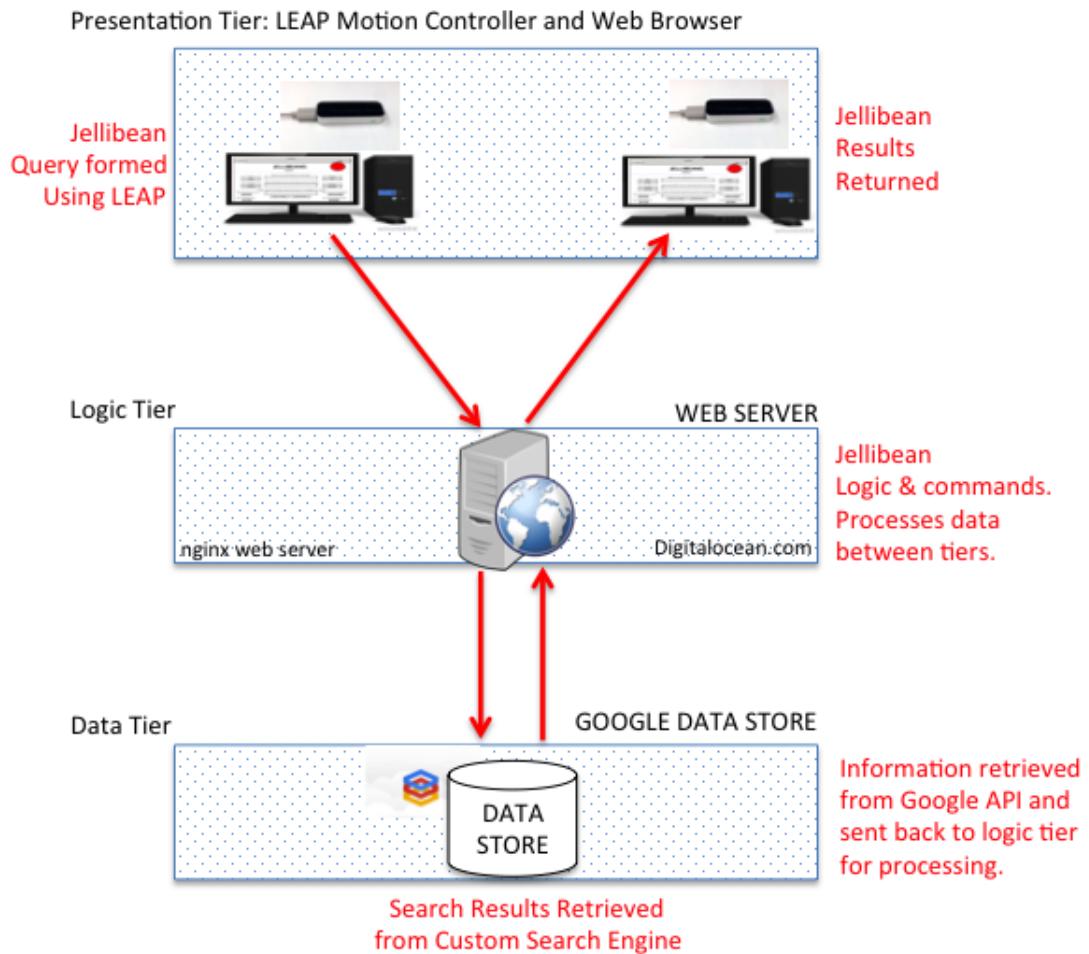

Figure 8: 3-tier architecture implementation

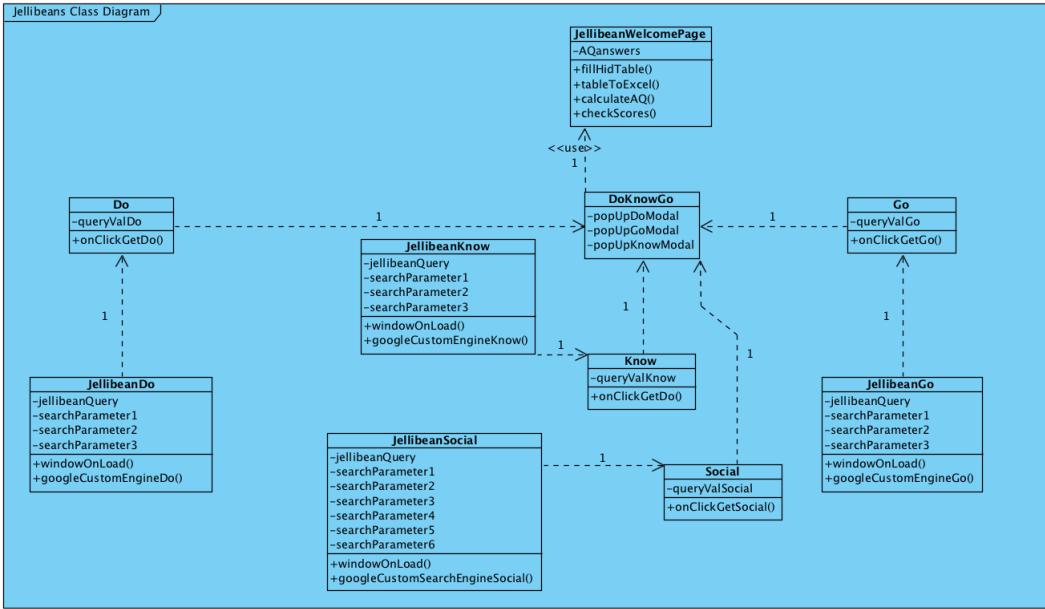

Figure 9: High Level UML Class Diagram of the Web Presentation Module

Classes that were implemented in the web presentation module can be seen in Figure 9.

At the logic layer, Jellibeans works to build user search queries from the elements on the web page. The parameters are entered by the user when they form their search query. The Builder Design pattern was used to retrieve parameters from the URL, build these into a complete search query, and submit these to the Jellibeans Custom Search Engine, so that the correct result pages can be returned to the user.

A use case diagram of the system can be seen in Appendix 9.1.

5 Software Development Process

To see a list of the API's, development languages used and their justifications, see Appendix 9.2. The APIs and languages are explained in the context they were used below.

5.1 Core Feature 1: Research and Data Collection for a Combination Search Engine using Google, Yahoo and Bing.

To implement the combination search engine I used three API's provided by Google, Bing and Yahoo, namely, the Google Custom Search API, Yahoo BOSS Java API and Bing Search API.

To get started with the Google Custom Search API, I created a project called *Jellibeans* in the Google Developers Console, and an OAuth 2.0 Client ID. I obtained a Consumer Key and Secret to use the API, and used these in the application code to access the Google Custom Search Engine (see Figure 10).

```
public class GoogleCustomSearchApiApplet {

    String qry = null;
    public ArrayList<String> jSoupGoogleLinks = new ArrayList<>();

    public void cse() throws IOException {

        String key = "AIzaSyCnAIDiZchNkR00TBH3NMNt4GmRiwpdnA"; // server key

        String cx = "008818185974073145685:ga_fmgk9gf0";
        URL url = new URL("https://www.googleapis.com/customsearch/v1?key=" +
            + key + "&cx=" + cx + "&q=" + qry + "&alt=json");
        HttpURLConnection conn = (HttpURLConnection) url.openConnection();
        conn.setRequestMethod("GET");
        conn.setRequestProperty("Accept", "application/json");
        BufferedReader br = new BufferedReader(new InputStreamReader(
            (conn.getInputStream())));

        String output;
        while ((output = br.readLine()) != null) {

            if (output.contains("\"link\": \"")) {
                String link = output.substring(output.indexOf("\"link\": \"") +
                    + "\"link\": \"").length(), output.indexOf("\","));
                jSoupGoogleLinks.add(link.toString());
            }
        }
        conn.disconnect();
    }
}
```

Figure 10: Jellibean Applet Combination Search Engine

Following that I also registered my JavaScript origins within the console to access the Google+ API, and redirected URIs so that once users Sign-In using their Google+ login credentials they will be redirected to Jellibeans (or <http://esha.mseth.co>). This was done because I wanted users to be able to sign in and access their google profile from Jellibeans (see Figure 11), giving the user the feel of a more person-

alised search experience.

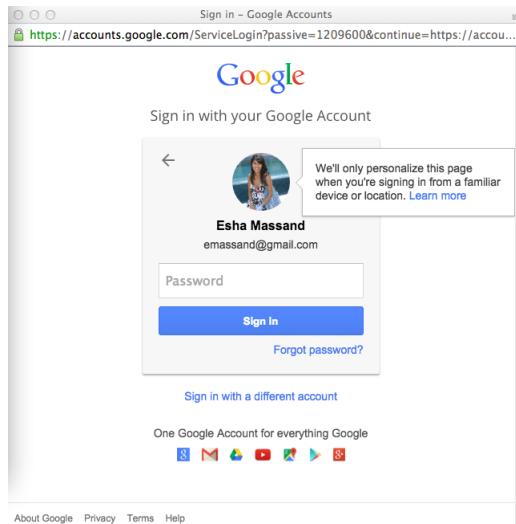

Figure 11: Google Sign In Pop-Up.

Following a similar protocol for Yahoo and Bing Search API's, I created projects in the Yahoo Developers Network, and Microsoft Azure Marketplace, and purchased an API Consumer Keys and Secrets (needed to use the APIs).

5.1.1 Web Scraping

As Web Scraping for Bing and Yahoo search (using the JSoup API) was an option, and it quickly became a preferred choice because of the flexibility/manipulation of the results if they were returned using the same API rather than two different ones. Web-Scraping is against terms of service set out by Google, however (see section 5.3 of Figure 12). Furthermore, the web-links that were returned using web-scraping on any Google results pages were erroneous and incomplete.

5. Use of the Services by you

5.1 In order to access certain Services, you may be required to provide information about yourself (such as identification or contact details) as part of the registration process for the Service, or as part of your continued use of the Services. You agree that any registration information you give to Google will always be accurate, correct and up to date.

5.2 You agree to use the Services only for purposes that are permitted by (a) the Terms and (b) any applicable law, regulation or generally accepted practices or guidelines in the relevant jurisdictions (including any laws regarding the export of data or software to and from the United States or other relevant countries).

5.3 You agree not to access (or attempt to access) any of the Services by any means other than through the interface that is provided by Google, unless you have been specifically allowed to do so in a separate agreement with Google. You specifically agree not to access (or attempt to access) any of the Services through any automated means (including use of scripts or web crawlers) and shall ensure that you comply with the instructions set out in any robots.txt file present on the Services.

5.4 You agree that you will not engage in any activity that interferes with or disrupts the Services (or the servers and networks which are connected to the Services).

5.5 Unless you have been specifically permitted to do so in a separate agreement with Google, you agree that you will not reproduce, duplicate, copy, sell, trade or resell the Services for any purpose.

5.6 You agree that you are solely responsible for (and that Google has no responsibility to you or to any third party for) any breach of your obligations under the Terms and for the consequences (including any loss or damage which Google may suffer) of any such breach.

Figure 12: Google Terms of Service

I used the Jsoup API [18], which is a Java-written API for HTML. The library provides methods to conveniently extract data using DOM (Data Object Model) and CSS (Cascading Style Sheet) methods.

The combined Google, Yahoo and Bing results were integrated these into a Java Applet that runs in Eclipse Luna IDE (see Figure 13). The program ran so that the user could enter a search query and the results would be presented back to them for inspection. The top 10 links, from each search engine were presented to users. Results were ranked prior to presentation, such that result 1 from Google was followed by result 1 from Yahoo, and that was followed by result 1 from Bing. Then results 2 from Google, Yahoo and Bing were presented and so on, until the 30 links were produced (top 10 links for a search from each search engine), in ranked order from the three search engines.

```

public void jsouphtmlYahoo() {
    Document doc;
    try {
        String searchPage = "https://uk.search.yahoo.com/search?p=";
        String tempSearch = searchPage + query;

        // need http protocol
        doc = Jsoup.connect(tempSearch).get();

        // get page title
        String title = doc.title();
        String selection = "#title > a";

        Elements links = doc.select(selection);
        for (Element l : links) {
            jSoupYahoo.links.add(l.toString());
        }
    } catch (IOException e) {
        e.printStackTrace();
    }
}

public void jsouphtmlBing() {
    Document doc;
    try {
        String searchPage = "https://www.bing.com/search?q=";
        String tempSearch = searchPage + query;

        // need http protocol
        doc = Jsoup.connect(tempSearch).get();

        // get page title
        String title = doc.title();
        String selection = "#h2 a";

        Elements links = doc.select(selection);
        for (Element l : links) {
            jSoupBing.links.add(l.toString());
        }
    } catch (IOException e) {
        e.printStackTrace();
    }
}

```

(a) JSoup HTML Parser.

5.1.2 User Research and Testing of Core Feature 1

To test the integrated combined search engine, 10 participants took part in a study to evaluate the quality of its output. The participants were selected because they scored highly (above 30, where 32 is threshold for Autism Spectrum Disorder with a 79% sensitivity) on a 50-item screening measure of Autism-like traits (the Autism Quotient [1]), and these individuals were thought to be most suited to test the current system.

The range of scores for the AQ is 0 to 50 with high scores indicating increased likelihood of autism-like traits. A score under 21 is a low to average result (many women average around 15 and men around 17). A score of 22-25 indicates autistic tendencies slightly above the population average. A score above 26 gives a borderline indication of high functioning autism, or Aspergers. A score above 30 suggests a likelihood of Aspergers syndrome or autism (sensitivity of test measure = 79% [1]). For the purposes of this study, individuals with scores equal to, and above 30 were interpreted as having 'autistic-like traits'.

Results from 10 pre-determined search queries were presented to the 10 participants and they were asked to comment on the search results that had been returned, and to choose three out of the links returned that they would follow up

with. They were also asked to observe if anything was odd about the results returned. The responses from the 10 users were analysed to determine whether a combination search would be an enhancement in Jellibean Search, or whether it would introduce redundancy in the search results.

Somewhat non-surprisingly (given the statistics of most preferred search engines (Google's unique monthly visitors: 1,100,000,000 and query volume: 64.5% ; Bing: 350,000,000, 12.8%; and Yahoo!: 300,000,000, 64.5% ([7] [20])), the results revealed Bing Search was favoured the least, and Google results the most, with Yahoo falling somewhere in between. Out of the 30 responses participants indicated to follow up with (3 per participant), 21 were Google results, 3 were Yahoo, and 1 was Bing and 5 results overlapped between Google and Yahoo. Four participants commented specifically, that the Bing results were distracting rather than helpful.

Given these findings from the user group, it was decided to continue using the Google results, but to drop the results from Yahoo and Bing, in line with the aim of the project as a whole, that is, to improve returned search results for users with Autism.

5.2 Core Feature 2: Building a User Model of Autism.

To identify the features of the user model to build, I ran a study to collect example search queries on a set of informational needs from 37 participants. The participants were asked to give examples of search queries they would use to, for example, identify the name of a song they had heard (given the lyrics), or the name of a breed of a dog they had seen (given a picture of the dog). There were in total 10 search queries; the study was distributed widely via Surveymonkey.com [26] and can be seen in the Appendix 9.3. All participants were also asked to complete the Autism Spectrum Quotient 50-item questionnaire see Appendix 9.4. The participants responses are analysed and reported back to surveymonkey.

Participants were divided into two groups; low AQ scorers (scores below 30), and high AQ scorers (scores equal to and above 30). There were 30 low AQ scorers and 7 high AQ scorers.

5.2.1 Differences in Search Queries Between Users With and Without Autistic-like traits.

I conducted a qualitative analysis on the search query strings from both low and high AQ scorers.

To confirm the results from the user testing of Core Feature 1, participants were asked to indicate which search engine they commonly use, and in both groups, Google was the preferred search engine by far, with all participants reporting that they used Google as a first choice. No one in the current sample used Yahoo or Bing.

The low AQ scorer responses were analysed together to establish a baseline answer. This was generated using a frequency criterion of 40% i.e., if 12 out of 30 respondents or more generated the same portion of a query string given an informational need, it was included in the model below. If two responses were equally as common, both are reported in the model. Data was discarded when a response indicated that the participant would do an image search, as this was not the aim of the survey. The results from the frequency analysis are presented below.

1. You hear a song on the radio with the lyrics, 'Look at your children', and you want to download it. What would you type into search on your favourite search engine to find out what song it was?
Look at your children song.
Look at your children lyrics.
2. You've lost touch with an old school friend (you went to St. Mary's School). What key words/queries would you use to find them?
St. Mary's School Year of X.
3. How would you identify what this is using a search engine (pretend you don't know what it is called). What key words/queries would you use?
Star shaped brown plant.
4. How would you find out the name of this famous person using a search engine? What key words/queries would you use?
Brown hair famous young women.
5. How would you identify what breed this animal is using a search engine? What key words/queries would you use?
Small dog fluffy breed.
6. Your friend and you can't agree on how Thandie Newton pronounces her first name. How would you resolve this using a search engine?
Thandie Newton pronunciation.
7. What would you search for to identify this pattern's name, and which country it originates from?
Repeating square maze pattern border.

8. How would you search for delay's relating to your (imminent) flight to Paris?

Flight number, carrier, Paris, airport, flight time.

The following observations were made for the users in the high AQ group:

- There were an increased number of incompletely-formed queries. In the high AQ group, participants were more likely to miss off words in the query string. For example, when analysing the results from query 1 above, 2 out of 7 respondents in the high AQ group did not put 'lyrics' or 'song' in the search query when searching for the lyrics "Look at your children". When these search strings are entered into Google, the results are very different (see Figure 14). A larger number of results are returned to the incomplete query (302,000,000 compared to 32,900,000). In this instance, the high AQ user group were presented with results that have a lower precision, i.e., more irrelevant information that they must sift through to find the answer to their search query.

(b) Complete query results.

Figure 14: High and low AQ scorers both formed search queries accurately, however there was an increased tendency to omit the word "lyrics" in the high AQ group resulting in very different search results.

2. Although many high AQ scorers' formed query strings well, there was increased use of idiosyncratic words in the query strings that were formulated. This is in line with previous research that suggests that people with autism organise information in more subjective and individual ways [4]. For example, referring to the picture of the dog as 'yorkie pooh'(not listed in frequency index), 'aeroplane' (frequency of 8254 words per million) instead of plane (frequency of 33900 words per million) or flight (29535 words per million), 'miniature' (less than 4973 words per million) instead of small (185463 words per million). The idiosyncratic nature of the words is captured by their lower frequency of use in the English language. Search engines use term frequency to determine if a document is relevant to the users search query. If the frequency of words used to form search queries differs between low and high AQ scorers, so will the rankings of the returned search results.
3. One individual of the 7 individuals in the high AQ group demonstrated ambiguous use of third-person pronouns, which is characteristic of some individuals with Autism [22]. This includes using first names. This is particularly detrimental to search engine query strings because the use of names disrupts the term frequency - inverse document frequency weighting [27] of the search query and subsequently the results returned to the user.
4. For questions that were 'social' in nature (e.g., featuring a face of a famous woman), 2 out of 7 individuals in the high AQ group indicated that these were types of queries that they would not normally be interested in, and so "wouldn't bother asking it". For these queries, it was more common for individuals in the high AQ group to include information in their search query string that was extraneous to the search question itself, compared to the low AQ group. For example, in query 4 above (which asked respondents to indicate how they would identify a famous person), 2 high AQ scorers included information about the woman's earring. Inevitably this 'dilutes' the search query and results in reduced precision for the search engine.

5.3 Core Features 3 and 4: Jellibeans – Transforming the User Query.

Given the set of observations in the data reported above, the aims were to 'transform' queries made by individuals in the high AQ group to queries more similar to the low AQ group. The search engines already handle some of the observations from high AQ scorer queries. For example, the use of pronouns ('I' and 'You') is already taken care of with the use of stop words. The aim of the project is to therefore address issues that result in the search query string being misleading, and returning different results to low AQ scorer search queries. The rule engine is a concrete and operationalised framework, for a theoretically-grounded

stereotyped user model of autism within search.

Jellibeans works to address multiple observations made during the data collection stage, so the order in which the observations are tackled in the user model is not linear. As a general rule, changes will take the form of ‘add on’ questions that aim to structure the individuals search query logically, so that key search terms are not dropped. A structured query formation will assist the user with less idiosyncratic search queries.

Building upon the research discussed in the introduction [10], that search can be compartmentalised into three broad categories (Do’s, Know’s and Go’s), and, to address the observation of idiosyncrasy (point 2 above in the current research), Jellibeans will prompt the user to categorise their search query into one of 3 possible types of queries, a ‘Do’, ‘Know’ or, ‘Go’. ‘Do’ queries are when they want to do something on the web like, buy a cinema ticket. ‘Know’ queries for when they want to know something from the web like, what time the cinema closes. And, ‘Go’ queries when they want to go somewhere specific on the web like the cinema homepage. Jellibeans will integrate a fourth subtype of query – the ‘Social’ query, especially for the user group in question. ‘Social’ queries are for when their search is about something social; a person, or group of people. Social queries have additional functionality beyond the Do, Know and Go query pages, to reflect the additional difficulties individuals with Autism have when formulating Social search queries on the web.

Each type of query will be associated with a different colour, and once the user has selected that type of query, this colour will be prominent on the page throughout their search, to serve as a visual reminder of the task. This works to reduce the **working memory load** for the user, and to serve as a **goal-directed cue**.

Two things we know are difficult for people with Autism are maintenance of information in working memory, and goal-directed tasks involving a high demand on Executive Functioning (Executive functions (also known as cognitive control and supervisory attentional system) is an umbrella term for the management (regulation, control) of cognitive processes, including working memory, reasoning, task flexibility, and problem solving as well as planning and execution [8].)

The Jellibeans ‘Social’ query applies particularly to the user group in question, and has hints and suggestions added into search to assist the user when forming their query. The cues take the form of suggestions, that the user may select if helpful for their search, and to improve search results that are returned from Jellibeans.

To address observation 1, that user queries were often submitted when incom-

plete, suggestions as well as drop down menus have been implemented on each search page. Users can click on suggestions, and select from the menus if they want the keyword to be added to their search. Individuals with Autism have an uneven cognitive profile, where verbal ability is usually lower than performance skill [6], the cues will assist users who have particular word-finding difficulties.

Once the user has pressed ‘Jellibean Search’, and requested their search results be returned, Jellibeans collates all information the user has entered into the search boxes, as well as any suggestions, and options from drop down menu’s that were selected to be included in the search. To achieve a good precision and specificity, Jellibeans implemented ‘AND’ boolean operators between each input of the parametric search. This resulted in increased precision and a drop in recall for Jellibeans. The results are then presented to the user, with the exact phrase that was searched for. This means that the user can clearly see their final search query, and rather than a ‘black-box’ system, Jellibeans also works to train the user for the long-term about specific ways to improve their personal search query strings.

Because the current research identified that user’s with Autism formed search queries were particularly incomplete for socially-grounded informational needs, extra functionality has been added to the ‘Social’ query page. For example, if the user has indicated that they are searching for a famous person, they will be prompted for descriptions about that famous person’s personality, character age bracket, and physical descriptions amongst other attributes. These features work to ensure that for this type of query, where users with Autism have most difficulty, that user search queries are more complete than they otherwise would have been (see Figure 15).

The screenshot shows a web browser window titled 'Social' with the URL 'esha.mseth.co/social.html'. The page has a large red circular logo in the top right corner. The main heading is 'JELLIBEANS' with the subtext 'FORM YOUR SEARCH QUERY'. On the left, there are several input fields and dropdown menus for specifying search parameters:

- Who are you searching for on the web?**
 - Male
 - Female
 - LinkedIn
 - Facebook
- What information do you want back from your search?**
 - Famous
 - TV
 - Musician
 - Comedian
- What is the person's hair colour?** Black
- What is the person's style?** Chic
- Enter specific information about the person to complete your query.**
- What is the person's age category?** Young
- Describe the personality of the person** Sexy

At the bottom are two buttons: 'Search in Google' and 'Jellibean Search'.

Figure 15: Example of User's Social Search in Jellibeans.

The Autism Quotient score and all 50 of the responses from the user will be stored locally to an Excel file, if the user chooses, by selecting the 'Save Your Answers' button on the Jellibean Homepage (see Figure 18).

Q37	If there is an interruption, I can't easily switch back to what I was doing.	
Q38	I am bad at social chit-chat.	
Q39	People often tell me that I keep going on and on about the same thing.	
Q40	When I was young, I did not enjoy playing games which involved pretending with other children.	
Q41	I like to collect information about categories of things (e.g. types of car, types of bird, types of train, types of plant, etc.).	
Q42	Find it difficult to imagine what it would be like to be someone else.	
Q43	I like to plan any activities I participate in carefully.	
Q44	I don't enjoy social occasions.	
Q45	Find it difficult to work out people's intentions.	
Q46	New situations make me anxious.	
Q47	I don't enjoy meeting new people.	
Q48	I am not a good diplomat.	
Q49	I am not very good at remembering people's date of birth.	
Q50	I find it very hard to play games with children that involve pretending.	

Figure 16: Example of User's Social Search in Jellibeans.

The user can also choose 'Calculate Your Score' which returns the score as an alert to the page

To further address Core Feature 3 of Jellibeans, that is, that results should be returned to the user in smaller snippets rather than large sets of text, I modified the Jellibeans Custom Search Engine to select the 3 highest ranked (pre-

cision) results, and to present these back to the user on the first page of their search. The 3 top results are presented on a floating modal³, so that the user has the option to close and reopen the results very easily, without having to redo the search itself (see Figure 7).

5.4 Core Feature 5: Integration with a Motion Controlled Interface.

The selection process for the hardware to integrate with Jellibeans considered 4 factors; the timing of the device, the ‘volume’, the applicability to real-world environments and the affordability for users.

Jellibeans is integrated with the LEAP Motion Controller Hardware (see Figure 17) which has good timing as it polls frames at a constant rate to keep to timing of accurate movement, and this is important for user experience. It is very easy to use and only requires a short calibration period. It is non-invasive and has a low sensory experience (sensory stimulation is not tolerated well by individuals with Autism). The cognitive demand needed to operate the LEAP is low, and given that web search is a highly cognitive task, this is of real benefit for the user.

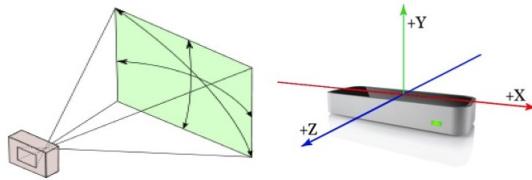

Figure 17: The LEAP controller, with 150 degree view [12].

The LEAP recognises and tracks hands, fingers, finger-like tools, positions, motions and gestures using infrared light and optical sensors along the cartesian coordinate system. The controller has a 150-degree field of view, and operates in a range of 1 inch to 2 feet.

Each of our senses operates with a different lag time. Hearing has the fastest sense-to-cognition/understanding, and surprisingly, sight – the slowest. If the device interferes with the processing of the sense, it will confuse the combinatorial configuration of the senses, leading to misunderstandings in the meaning and a worse user experience. The LEAP does not have the best cognitive lag time compared to other devices such as the Oculus VR Rift. However, for Jellibeans, the browser refresh rate will likely be the biggest bottleneck for performance, rather than the motion-controller chosen. The LEAP is a completely non-invasive

³A modal is a feature in the Bootstrap Framework, for more information see Appendix 9.2

in comparison to the Rift (see Figure ??), so it was considered a better option for the current user group.

LEAP reference: <http://edition.cnn.com/2013/07/22/tech/gaming-gadgets/leap-motion-controller-review/>

Oculus VR Rift reference: <https://www.maxxor.com/blog/past-future-oculus-rift/>

Figure 18: Comparison of the invasiveness of the Oculus VR Rift and LEAP motion controller.

I also took into consideration the way in which the device manifests actions into behaviours. That is, how does the user engage behaviourally within the environment using the device? The LEAP was considered very realistic in terms of the transition of behaviour into real-world environments.

5.4.1 Using LEAP in the IDE.

Frames (cartesian coordinate data) from the LEAP were tracked using the Frames class, and detected user motions. The following code was used to implement a forward-poking pointing motion to control mouse clicks. I ran the code to check how well it worked in Eclipse IDE (see https://youtu.be/ikfiul_JPBk for a video of the LEAP working in my IDE).

```
Controller JellibeanController = new Controller();
Frame jellibeanFrame = JellibeanController.frame();

Robot jellibeanRobot = new Robot();

if(jellibeanFrame.fingers.get(arg0).tipVelocity.get(2)>75)//if finger moves forward past a threshold velocity {

    jellibeanRobot(InputEvent.BUTTON1_DOWN_MASK);
    Thread.sleep(200);
    jellibeanRobot(InputEvent.BUTTON1_DOWN_MASK);

}
```

Figure 19: Pointing and Poke Motion Used to Control Mouse Clicks.

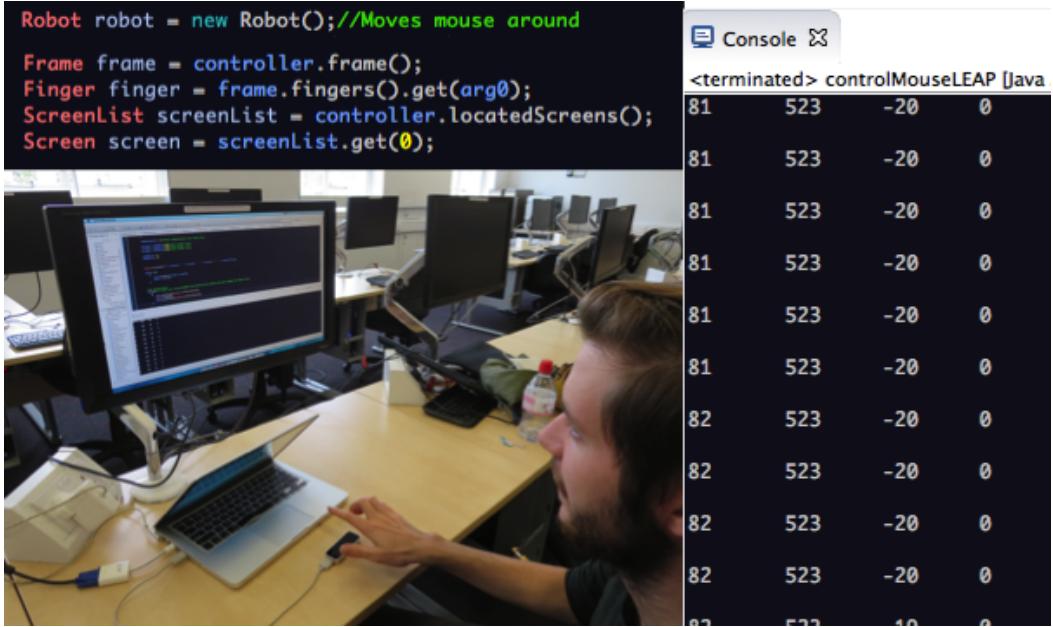

Figure 20: Using the LEAP to Control the Cursor in the IDE.

Although using the device this way was interesting and novel, the user has little control over the cursor, and often hand movements aren't precise enough to have a good experience using the hardware. I decided to look for a library that I could use with the LEAP to overcome this. One such library is Leapstrap which I discuss in the next section.

5.4.2 Using Leapstrap in the Web-browser.

To use the LEAP in a web-browser I used Leapstrap [13], which is built on top of Bootstrap and was easy to integrate into the project. To integrate Leapstrap into the HTML I added link in the Leapstrap CSS , jQuery, Leap.js and Leapstrap.js. I also initialised the Leap in the body of the HTML code, and finally made all elements of the class “leap-interactive” (see Figure 21).

```

In the head section of the HTML page:
<!-- Include Leapstrap CSS -->
  <link rel="stylesheet" href="//wilkesalex.github.io/leapstrap/dist/css/leapstrap.css" />
<!-- Include jQuery -->
  <script src="//ajax.googleapis.com/ajax/libs/jquery/1.10.2/jquery.min.js" ></script>
<!-- Include Leap -->
  <script src="//js.leapmotion.com/0.3.0-beta3/leap.js"></script>
<!-- Include Leapstrap JS -->
  <script src="//wilkesalex.github.io/leapstrap/dist/js/leapstrap.js"></script>

Before the closing </body> tag:
<!-- Init Leap, Set all "a" interactive, use 1 Leap cursor/finger -->
  <script>LeapManager.init({interactiveSelector:"a",maxCursors:1});</script>

And, every element must be assigned to the class "leap-interactive":
<a class="leap-interactive" href="#">Click me with Leap!</a>

```

Figure 21: LeapStrap Library to Implement the LEAP for Jellibeans.

Once the LEAP was enabled for the web browser I was able to test Jellibeans with users to gather feedback.

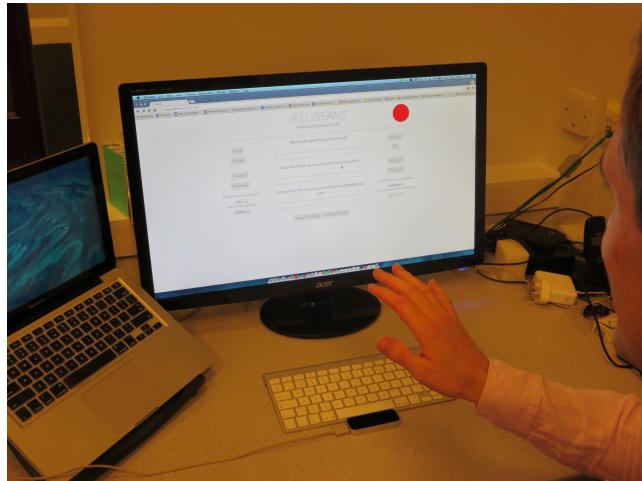

Figure 22: User Forming A Jellibean Search Query with LEAP Using One Hand.

5.4.3 Evaluation of the LEAP Motion Controller in Jellibeans.

The LEAP motion controller is an impressive device that uses infra-red light to embed the users (phantom) hands onto the screen. It is a novel, ‘at home’ technology, and because of the portable nature of the device, it is one that has been introduced to laptops. The LEAP offers a recalibration process if the controller is persistently jumpy, which is good because jumpy movements and mannerisms could be an issue for some of the users in the current user group. The device will recalibrate if there are discontinuities or aberrations in the tracking data in

certain field of view, or in poor tracking ranges.

The LEAP does however miss small hand movements, and also very large ones (outside of the 150 degree angle along the y axis (see Figure 17)). The LEAP also neglects to track the bottom left and right-most corners of the screen. I have tried to take this into consideration when designing Jellibeans, so that the user does not need to reach to the corners of the screen.

6 Software Testing

I used Behaviour Driven Development (BDD) to test the integration of my HTML, CSS and JavaScript code. The testing process consisted of development, test, make modifications, test (and so on) until the behaviour of the website was what I intended.

The JavaScript Console was used for testing JavaScript code. [16], I also used JSfiddle [17] to ensure the code contained no bugs, and was particularly good for seeing how the JavaScript code integrated with the HTML code and CSS.

JUnit was used to test the Combination Search Engine and the LEAP motion controller methods, which were written using Java. Unit testing was completed, at the method level.

7 User Verification and User Testing

Five high AQ scorers were called back from the previous research study for one-to-one interviews and a combined focus group. During the interview, individuals were given the same user search queries as previously, and for each search that was implemented, users were asked to comment on whether it enhanced, or took away from their search experience, and from their satisfaction with the search results. Users were asked to comment on:

1. Whether the colour coding for each category of search was helpful.
2. Whether they liked the parametric search style of Jellibeans
3. Whether they felt Jellibeans ‘narrowed’ the scope for irrelevant detail.
4. If they would choose Jellibeans over other search engines, for example, Google, and why.
5. The speed and efficiency of search with Jellibeans

6. Their thought on search results.
7. The integration of Jellibeans with the LEAP motion controller.

7.1 The Positives

All 5 users verified that the 'Dashboard' colour coding was helpful (see Figure 24), and liked that the colour of the chosen type of search remained on screen for its duration.

Figure 23: Colour coding on Jellibeans dashboard.

The modals (floating window reminders) for each of the colour themes were useful for all new users, as they were originally unfamiliar with the colours. The associations for all user groups, including users with Autism, were quick to learn, these were single link visual (rather than verbal) associations.

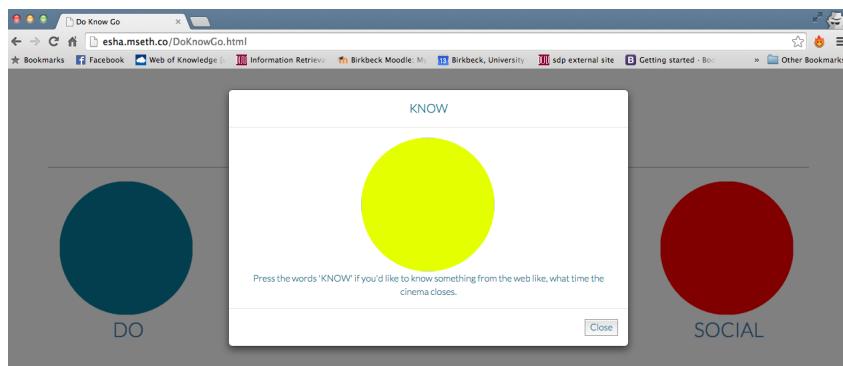

Figure 24: Modals Assist New Users To Learn the Colour Associations.

Four out of 5 participants agreed that one of the major positives of Jellibeans was that unlike Google, users did not receive back hundreds and thousands

of mostly irrelevant results. Jellibeans held their interest for longer because of the reduced number of results that users had to sift through. Testing also revealed that the parametric search style meant that they did not need to try and remember all the key words to search for, rather the cues helped them remember points they would have missed otherwise.

A common comment (3 out of 5 users) was the time/reward payoff from completing a detailed search form. Users agreed that although they would spend more time formulating their search query, they were likely to save time that would usually be spent sifting through search results. These participants indicated that they would use Jellibeans over other search engines if continued use on other queries also showed such benefit.

All users positively commented on the reduced number of search results presented (top 3). The amount of textual information that was presented back on the results page is significantly reduced in Jellibeans.

During the focus group one user with high functioning Autism described that the direct questions (e.g., ‘What do you want to do on the web?’), with suggestions ('Shop', 'Watch', 'Listen'), was useful when he was “at a total blank”. He disclosed that often his need for perfectionism and sameness could have him staring at a blank screen until he came up with the ‘perfect’ query. However, the suggestions were helpful for him to get started, and so his experience was that the queries were completed faster than usual.

7.2 The Negatives

Two users however, had considerations about the ‘missing’ results from their search and commented that for them, 3 results were too few and perhaps 5 or 6 results would have been a better choice. It must be said that these individuals were amongst the lowest AQ scorers, suggesting that the amount of text individuals with Autism find optimal is a function of the severity of Autism traits in that individual.

One participant commented that the suggestions that appear on the sides of the ‘Do’, ‘Know’, ‘Go’ and ‘Social’ pages were not user-specific (see Figure 25). He suggested implementing something that is user-centred, user-driven, or, trending, rather than static.

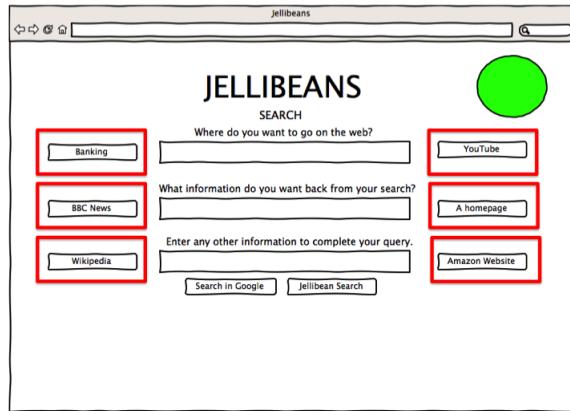

Figure 25: Suggestions on Jellibeans 'Go' page for users to help with search query formulation (suggestions are highlighted in red).

However, one of the characteristics of Autism is restricted and repetitive behaviours, and an aim of the current project was to reduce the restricted and repetitive nature of search queries for people with Autism. In other words, this comment was suggesting that Jellibeans was achieving the aim it had set out to do.

Nevertheless, one future direction for Jellibeans in order to achieve a balance between user-specific suggestions but not restricted interests, is to include a recommendation system that changes often enough for them not to be repetitive, but still within a range of possible interests for that individual.

7.3 The Neutrals

Users agreed during the focus group that with Jellibeans the time/reward payoff is really only apparent, over and beyond a traditional search engine, when the search query is complex. For example, if users are searching for something they have yet to identify, i.e., something ambiguous. To overcome this criticism, Jellibeans includes a 'Search in Google' option, so that if users know what they are searching for, they have the option to run the search outside Jellibeans.

8 Evaluation and Discussion.

The final section summarises the project as a whole. A critical evaluation by the student, emphasising strong points and weak points, lessons learnt, design decisions which, looking back, would be made differently, ways in which the project could be improved or extended etc. recommendations for the project. You can also describe possible future work in the area of your project.

Robots Apache Lucene Sandboxes JavaScript html can't access third party pages

design decisions which, looking back, would be made differently ways in which the project could be improved or extended etc.

recommendations for the project

You can also describe possible future work in the area of your project

8.1 Signals of Quality Content

I will test and evaluate the system. Testing will involve assessing the reliability and robustness of Jellibeans; the ease of its interaction; boundary conditions; ease of use; does it fulfil the aims of the project. Evaluation of the system will include comparisons to existing search engines; assessing how this idea can be implemented to tailor an existing systems; assessing how well the system does compared to existing systems on a set of criteria that are only relevant to the user group in question (a collective measure of user happiness). Evaluation will also include quantitative metrics such as Recall, Precision, and False Negative/Positive rates.

Apache Solr

8.2 Future Directions

A future direction for Jellibeans would be to use an API or library for word frequencies in the written English language, which could be integrated with a thesaurus. This type of API requires significant research into the natural language processing of written (rather than spoken) English text. These frequency data could have been used to replace infrequent words in queries formed by individuals with Autism with more frequent words to suggest alternatives for the user. Of course this product would not be scalable, and only apply to users with a particular dialect. This is because word frequency is considerably variable across, and even within a language (e.g., consider South-West England compared to the North of England).

Another future direction for Jellibeans would be to implement current trending searches, which could be a contributing factor in the future for why users choose other search engines over Jellibeans.

Individuals with Autism have increased comorbidity with Attention Hyperactivity Disorder (ADHD), and Colour Blindness, and so these can be taken into account for future iterations of Jellibeans. For example, the colours used for Jellibeans are in the RGB colour scheme, but these could be replaced with gradients or patterns so that individuals with colour blindness can also benefit.

9 Appendices

9.1 Use Case Diagram

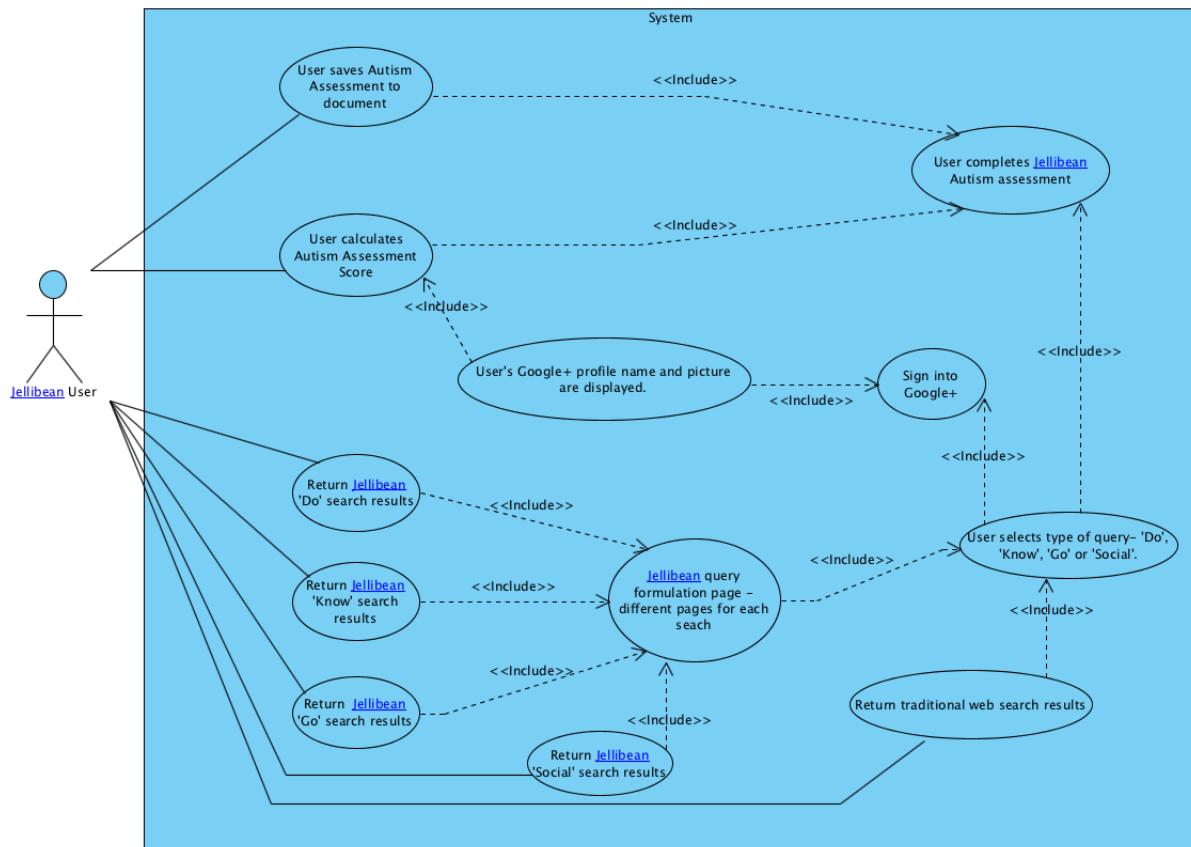

Figure 26: Jellibean Feature Uses and High Level UML Use Case Diagram

9.2 APIs Used in Jellibean Implementation

Google Search API	A RESTful API with a single method called list. The API method used was GET, and the response data is returned as a JSON type. The response consists of (1) the actual search result, (2) metadata for search like number of results, alternative search queries, and (3) custom search engine metadata. Google terms of service, state that ‘screen scraping’, or copying the data directly from the website is prohibited.
JSoup API	For Bing and Yahoo search results, JSoup (a Java HTML parser) was used to identify the links from the resulting query. The JSoup HTML parser was considered more efficient for retrieving search results, as it could be used to complete the task from both search engines, using a slightly different href element filter for each. JSoup also has advantages over html parsing. It contains a class representing a list of nodes called ‘Elements’, which implements Iterable to iterate over a list in an enhanced for loop.
Java	To test the combined output from the three search engines with a group of users, and gather their feedback on the results, I developed a Java Applet to run the programme. The search results from the Java Applet were written to a text file. Java was chosen for development of ‘to be tested’ packages of features (e.g., the combination search engine). The developer for the project was most proficient with Java, and could quickly develop prototypes for user testing.
JavaScript	JavaScript is commonly used in HTML as it can run locally in a browser (rather than remote server). The Google+ API provided good documentation for using JavaScript. Furthermore the JavaScript code could be easily embedded into the Jellibean HTML code to interact with the Document Object Model (DOM) of the page. The browser was able to respond to user demand quickly, which made Jellibeans more responsive. JavaScript was used in this way to return the aboutMe profile information from Google+ to the user.
HTTP Set-Up	The Hypertext Transfer Protocol (HTTP) enables communications between web-browsers (clients) and the server (the computer that hosts Jellibeans) using a request-response protocol. Jellibeans was deployed in textbfnginx HTTP web server, and digitalocean.com was used to host the web servers, so that it was ready to be used remotely by users (and for me to gather feedback easily). When the user submits a HTTP request to the server that hosts Jellibeans, it responds with the appropriate behaviour to the client so that the user can formulate their search query and retrieve the results from their search.

HTML	HyperText Markup Language (HTML 5) was used to create the webpages for Jellibeans, so that the web browser could render the website.
Bootstrap and CSS	For front-end development and to style the Jellibean web pages I used the Bootstrap framework [2] for it's clear styles, good design and ease of use for the current project. I included my own Cascading Style Sheet (css file) where I needed extra styling beyond what the Bootstrap framework could offer.
LEAP SDK	The LEAP motion controller is a light-weight, portable device that detects user motions using infra-red light. The LEAP has accurate timing, and works well with the combinatorial configuration of senses (sight, hearing and touch). As this is a tool to be used with individuals with Autism, who have increased sensitivity to touch, the LEAP is the perfect choice as there is no additional sensations to the users body. The LEAP is affordable for users to integrate with search at home, and currently retails for about \$60.
LeapStrap	The LeapStrap SDK was used to integrate the LEAP into the web browser. LeapStrap is a HTML5 front-end framework for websites, and gives them full LEAP motion functionality.

9.3 Search Query Survey

Search Behaviours

Welcome to My Survey

We are trying to understand more about how people with autism, or autistic tendencies, and people without autism search the web.

For the search queries below please indicate what search terms you would use to search the web.

There are no right or wrong answers.

Some of the searches do not have an answer but please tell us how you would go about trying to search for the answer.

If you would do many iterations of search, please indicate that below. Start with the one you are most likely to try.

Please indicate as much as you can about your search process as possible. Use as much space as you need.

There are 10 questions here and this should take approximately 20 minutes or less.

The second part asks you to complete an online questionnaire and report back the score on this sheet.

If you have any questions you can contact e.massand@bbk.ac.uk.

Search Behaviours

An Example Question

EXAMPLE QUESTION:

You saw a man reading the paper today (you don't know which paper it was), and the headline was vaguely about a new discovery about the solar system. What would you type into search on your favourite search engine to find out about the story?

EXAMPLE ANSWER:

I could start by searching, 'solar system and discovery and news and today'.

If that doesn't work I could search, 'todays paper and solar system', or if I don't find my answer there I could search 'news' and manually /visually sift the page for relevant info.

Search Behaviours

2. You hear a song on the radio with the lyrics, "Look at your children", and you want to download it. What would you type into search on your favourite search engine to find out what song it was?

3. You've lost touch with an old school friend (you went to St. Mary's School). What key words/queries would you use to find them?

4.

How would you identify what this is using a search engine (pretend you don't know what it is called). What key words/queries would you use?

5.

How would you find out the name of this famous person using a search engine? What key words/queries would you use?

6. Two repeats shown

What would you search for to identify this pattern's name, and which country it originates from?

7.

How would you identify what breed this dog is using a search engine? What key words/queries would you use?

8. Your friend and you can't agree on how Thandie Newton pronounces her first name. How would you resolve this using a search engine?

9. How would you search for information relating to your (imminent) flight to Paris?

10. <http://aspergerstest.net/aq-test/>

Go to the link above and report back your score on the Autism Quotient. There are 2 formats, please take 'AQ Quiz Option 1'.

Figure 27: Search Query Survey on Surveymonkey.com [26]

9.4 Questions on the Autism Spectrum Quotient [1]

Participants are asked to read each statement very carefully and rate how strongly they agree or disagree with the statement (Strongly Disagree, Slightly Disagree, Slightly Agree, or, Strongly Agree).

I prefer to do things with others rather than on my own.

I prefer to do things the same way over and over again.

If I try to imagine something, I find it very easy to create a picture in my mind.

I frequently get so strongly absorbed in one thing that I lose sight of other things.

I often notice small sounds when others do not.

I usually notice car number plates or similar strings of information.

Other people frequently tell me that what I āCnāDve said is impolite, even though I think it is polite.

When I'm reading a story, I can easily imagine what the characters might look like.

I am fascinated by dates.

In a social group, I can easily keep track of several different people āCnāDcs conversations.

I find social situations easy.

I tend to notice details that others do not.

I would rather go to a library than a party.

I find making up stories easy.

I find myself drawn more strongly to people than to things.

I tend to have very strong interests which I get upset about if I can't pursue.

I enjoy social chit-chat.

When I talk, it isn't always easy for others to get a word in edgeways.

I am fascinated by numbers.

When I'm reading a story, I find it difficult to work out the characters' intentions.

I don't particularly enjoy reading fiction.

I find it hard to make new friends.

I notice patterns in things all the time.

I would rather go to the theatre than a museum.

It does not upset me if my daily routine is disturbed.

I frequently find that I don't know how to keep a conversation going.

I find it easy to read between the lines ĀI when someone is talking to me.

I usually concentrate more on the whole picture, rather than the small details.

I am not very good at remembering phone numbers.

I donāCnāDt usually notice small changes in a situation, or a person āCnāDcs appearance.

I know how to tell if someone listening to me is getting bored.

I find it easy to do more than one thing at once.

When I talk on the phone, I'm not sure when it's my turn to speak.

I enjoy doing things spontaneously.
I am often the last to understand the point of a joke.
I find it easy to work out what someone is thinking or feeling just by looking at their face.
If there is an interruption, I can switch back to what I was doing very quickly.
I am good at social chit-chat.
People often tell me that I keep going on and on about the same thing.
When I was young, I used to enjoy playing games involving pretending with other children.
I like to collect information about categories of things (e.g. types of car, types of bird, types of train, types of plant, etc.).
I find it difficult to imagine what it would be like to be someone else.
I like to plan any activities I participate in carefully.
I enjoy social occasions.
I find it difficult to work out people's intentions.
New situations make me anxious.
I enjoy meeting new people.
I am a good diplomat.
I am not very good at remembering people's date of birth.
I find it very easy to play games with children that involve pretending.
